WORKSHOP RAINSMORE/SWOT

SEMANTIC SEGMENTATION OF SATELLITE IMAGES VIA DEEP NEURAL NETWORKS

Valdivino Alexandre de Santiago Júnior

- Coordenação de Pesquisa Aplicada e Desenvolvimento Tecnológico (COPDT)
 - Instituto Nacional de Pesquisas Espaciais (INPE)
 - São José dos Campos, SP, Brazil

- It is a task! Precisely, a dense prediction task!
- Pixel-based classification: every pixel matters!

Why is this important for remote sensing?

1 km

QUEIMADAS also rely on 30 m spatial resolution images. Still low resolution.

But, today we have very high-resolution sensors in satellites.

Ex: KOMPSAT 3/3A satellite, Korea Aerospace Research Institute (KARI): 50 - 70 cm.

WORKFLOW FOR IMAGE SEMANTIC SEGMENTATION AT INPE (SIMPLIFIED)

- 1.) Download the images (separated bands) from:
 - http://www2.dgi.inpe.br/catalogo/explore.
- 2.) Compose the bands (QGIS).
- > 3.) Generate images patches by cropping the entire scene. It results in patches of dimensions of 128 x 128, 224 x 224, 256 x 256 pixels.
- 4.) Generate the masks for each image patch.
- 5.) Train the deep neural network (DNN) model for semantic segmentation. The model receives image patches and the corresponding masks of the training and validation datasets.
- 6.) Evaluate the performance of the model (inference phase). The model receives only the image patches of the test dataset and predicts the masks. Metrics: pixel-based accuracy, pixel-based F1-score, mean Intersection over Union (IoU).

PATCHES AND MASKS

During the training phase, the DNN receives ...

PATCHES AND MASKS

During the training phase, the DNN receives the image patches and masks.

PATCHES AND MASKS

masks.

During the inference phase, the DNN receives the image patches and predicts the

- It is a convolutional neural network (CNN).
- U-Net's main characteristics [1]:

 - localisation (U-shape);
 - Strong use of data augmentation (few images);
 - 23-layer deep fully convolution network (FCN).

Cell Tracking - IEEE International Symposium on Biomedical Imaging (ISBI 2015): 1st place.

Suitable for semantic segmentation. But it can also be used for classification;

Contracting path to capture context and symmetric expanding path for precise

- Semantic segmentation classifies at pixel-level. Good: spatial dimensions of the input and output are the same.
 - Channel dimension at one output pixel can hold the classification results for the input pixel at the same spatial position.

Thus, some types of CNN layers can be used to increase (upsample) the spatial dimensions of intermediate feature maps, after the spatial dimensions are reduced (downsampled) by previous CNN layers.

2x2 max pooling (stride 2).

No FC layer at all!

output segmentation

Biomedical domain (others too): not huge number of images available.

Localisation: label for each pixel and not for the entire image (each pixel matters)!

Label for each pixel: using a local region (patch) around the pixel as input.

output segmentation

Training: in order to minimise the overhead and make maximum use of the GPU memory, large input tiles were selected over a large batch size. batch = 1 image.

output segmentation

Currently, there are several versions of the U-Net: See Ref [2].

Contextual classification (not semantic segmentation here).

Study site:

Nine damns of state of São Paulo.

Training dataset: CBERS-4 PAN10M sensor (10 m of spatial resolution).
